Crypto Lab 1 - Shishir Vuppala

Challenge 6: Canis Lupus Familiaris

flag: `cs409{p4dding_0racl3_l3aks_m0r3_th4n_y0u_1ma9in3}`

Solution

I just followed the strategy described in this website to use padding checks to figure out what the plain text is.

By modifying the previous ciphertext block and observing whether the padding is valid, we can determine the corresponding bytes of the plaintext one at a time. This is what the `decrypt_block` function does in my code. We run this function on all the ciphertext block and previous block pairs to recover the complete plaintext. Finally, we remove the padding from the recovered plaintext to obtain the flag.

Code

The script used to solve this challenge is written in `solution_template.py`
